## PREFACE

This paper has been prepared during periods the authors spent together in England and Denmark. We are very grateful for financial assistance with travelling expenses and publication contributed by the Director of the Geological Survey of Denmark (DGU), Dr. OLE BERTELSEN, by Sir John Cass College and by the Inner London Education Authority.

We would like to acknowledge the kind hospitality of Dr. JOHN W. NEALE of the Department of Geology, University of Hull, who made it possible for us to examine the Dorset type material. We would also like to thank Dr. R. H. BATE, British Museum (Natural History) who lent us type material from the Portland Sand of Dorset.

Finally we must express our appreciation to Mrs. RIGMOR BORG, Head of the Drawing Office of the D.G.U., to Mr. CHR. WESTERGAARD, and to Mr. O. NEERGAARD RASMUSSEN, D.G.U. photographers, for their invaluable assistance with the illustrations.

London, 6th February, 1970.

## ABSTRACT

The chronostratigraphical type profile of the Kimmeridgian of Dorset is subdivided biostratigraphically into five ostracod zones. Six other areas in Northern and Western Europe with Kimmeridgian ostracods are examined. The species are listed, counted, and examined in relation to the zones of the type Kimmeridgian.

In the Lower Kimmeridgian the ostracod faunas bear the impression of a relatively uniform composition between the examined areas. In the Upper Kimmeridgian two different faunal regions are developed. In the North Sea Basin in the North Western Danish Embayment and in Dorset relatively uniform faunas occur, separated from other, again rather uniform faunas occurring in the Mid-European Region, from Northwestern Poland and Scania to the Paris Basin.

Stratigraphically important are species of the genera *Galliaecytheridea*, *Mandellistamia*, and *Macrodentina*. 19 species are given diagnoses. Two new subgenera and seven new species are established.

## INTRODUCTION

The aim of this paper is to attempt to utilize ostracod faunas for biostratigraphical correlations in the Kimmeridgian of Northern and Western Europe. During the last two decades a considerable amount of information has accumulated about the Kimmeridgian ostracods of this area, and although the various areas are documented to varying degrees it seems possible at this stage to give an outline of the biostratigraphy. Seven areas of Northern and Western Europe are considered (fig. 1):

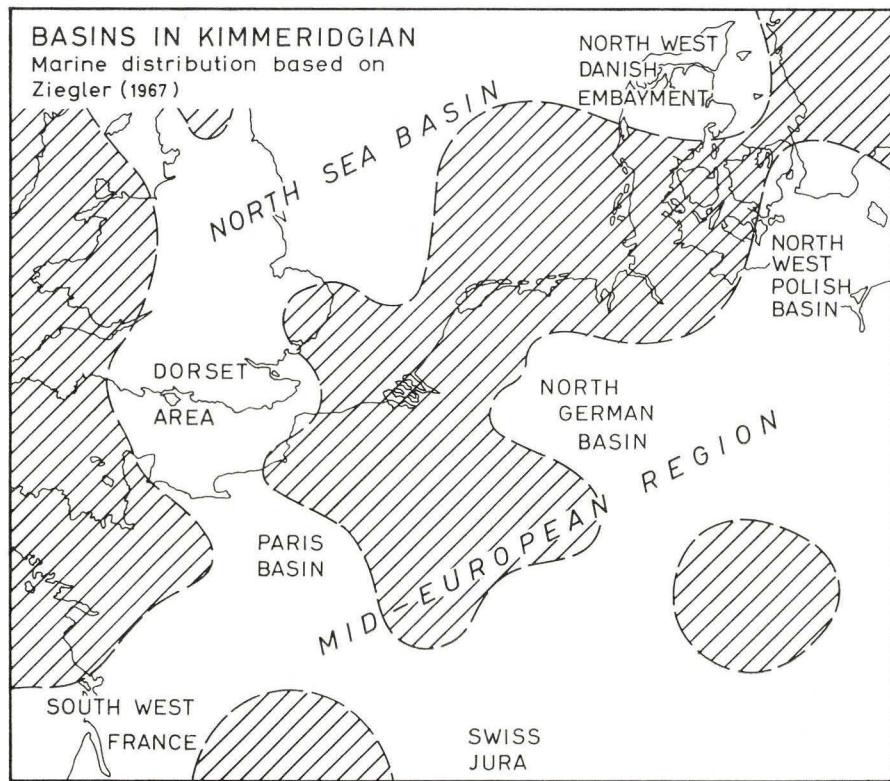

Fig. 1.

- 1 Dorset
- 2 North German Basin
- 3 North West Polish Basin
- 4 North West Danish Embayment
- 5 Paris Basin
- 6 South West France (Ile d'Oleron)
- 7 Swiss Jura

A full list of ostracods described from these areas is given on p. 27. The list includes some, but not all the forms treated with open nomenclature and nomina nuda. Some of the most important species are given full synonymy and diagnosis. In addition six species are described as new and species mentioned with open nomenclature will be described in the near future (BRUUN CHRISTENSEN MS).

The type section of the stage (the Dorset Kimmeridge Clay) is divided into five distinct ostracod zones and the other areas are correlated with the type section. The degree of similarity between the faunas of the different areas is also examined and its palaeogeographical implications discussed.

Throughout the paper the term "Kimmeridgian Stage" is used in the English sense.

### THE USE OF OSTRACODS IN STRATIGRAPHY

Ostracods have been used in stratigraphy with varying degree of success in the past. Species of the fresh-water genus *Cypridea* for example furnish many good and precise local range and assemblage zones in the Upper Jurassic and Lower Cretaceous Purbeck-Wealden type deposits. Marine ostracods are, however, on the whole relatively slowly evolving organisms and their geographical distribution is strongly influenced by facies – as is the case with most benthonic fossils. Biostratigraphy based on marine-brackish ostracods, therefore, cannot equal the precision afforded by the use of quickly evolving as well as quickly migrating planktonic and nektonic organisms (Ammonoidea etc.) The great advantage of ostracods in biostratigraphy is the wealth of marine and marine-brackish species which are not effected by a certain deviation from the standard marine salinity. This is particularly important in the Upper Kimmeridgian where in the areas considered – with the exception of Dorset – ammonite faunas are scarce or totally absent. Furthermore, in the study of material from boreholes one is restricted to microfossils.

As stated above marine-brackish ostracods have only rarely been used as indicators of range zones. The five ostracod zones designated in the type section are used in the sense of assemblage zones.

## THE KIMMERIDGIAN STAGE

The type section of the Kimmeridgian Standard Stage is the formation of Kimmeridge Clay of Dorset. The formation was first recognized and named by WEBSTER (1816) as "Kimmeridge Strata", followed by FITTON (1836) who first used the term "Kimmeridge Clay". The maximum thickness of the Kimmeridge Clay in Dorset is approximately 500 metres (ARKELL 1956) of which about 325 metres is exposed in the main type section (Kimmeridge Bay-Chapman's Pool). The lowermost parts are exposed further to the West in the neighbourhood of Osmington Mills where the thickness of the formation is somewhat reduced.

Lithologically the Kimmeridge Clay is a very uniform formation, consisting of dark shales and clays with occasional hard cementstone bands which are quite persistent horizontally and may be used as reference horizons locally. The shales and clays contain abundant ammonites (mostly flattened or crushed) and in certain horizons brachiopods and bivalves may be quite common. The hitherto used ammonite zonation of the Kimmeridge Clay (ARKELL 1933, 1947) is now being revised and the zonal scheme used in fig. 2 is based on ZIEGLER (1962), COPE (1967, 1968), CASEY (1967) and COPE, HALLAM, THORRENS et al. (1969).

When D'ORBIGNY (1842–1849) introduced his Jurassic stages he took the Kimmeridge Clay of Dorset as the type section of his "Étage Kimmeridgien" and the following Portland Sand and Portland Stone formations as the basis of his "Portlandien". Due to his misidentification of *Gravesia* (which occurs within the Kimmeridge Clay) from calcareous deposits in Germany and France as the large titanitids of the English Portland beds a dual and very misleading usage of the term Kimmeridgian Stage had arisen. In the British literature the Kimmeridgian Stage extends up to the *Albani* Zone (base of the formation of Portland Sand in Dorset) whereas on the continent beds containing *Gravesia* are included in the "Portlandian" Stage. Thus the Lower Kimmeridgian of Dorset became synonymous with the whole of the Kimmeridgian of the continent and the Upper Kimmeridgian of the British terminology with the Lower Portlandian of the French and German authors. This dual and undesirable usage of the term still persists in the modern literature. As the type section of the stage is the Dorset Kimmeridge Clay throughout this paper the Kimmeridgian Stage is based on the whole formation.

ARKELL (1933) divided the Kimmeridge Clay (and thus the Kimmeridgian Stage) into a Lower and Upper division, taking the "Yellow Ledge Stone Band" as the line of division. In this sense he included the *Gravesia* Zone into the lower division. Later ARKELL (1947, p. 66) follows the same classification but in the same paper (table on p. 67) he includes the *Gravesia* Zone in the Upper Kimmeridge Clay. In his "Jurassic Geology of the World"

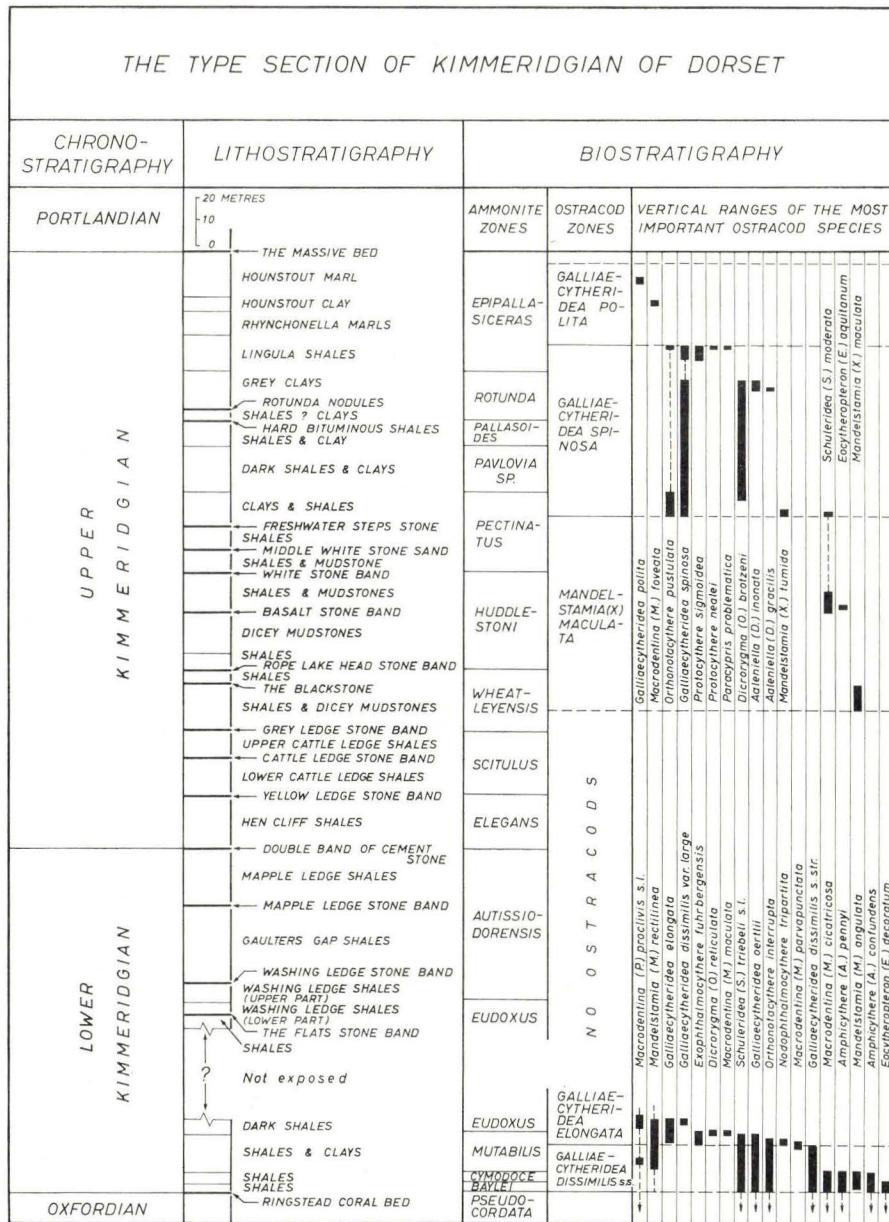

Fig. 2.

ARKELL (1956) introduces a threefold division of the formation, and the stage, the *Gravesia* Zone forming the base of the Middle division. Cope (1967, p. 4, footnote) states that "the Middle Kimmeridgian of ARKELL (1956, p. 21) has ... no real standing", and draws the boundary between the

Lower and Upper Kimmeridgian at the top of the *Aulacostephanus autis-siodorensis* Zone (base of the “Hen Cliff Shales”, see fig. 2 p. 12). This has been used as the “Kimmeridgian/Portlandian” border on the continent. The vertical distribution of ostracod faunas also suggests that the twofold division of the stage is more practicable.

## THE OSTRACOD ZONES OF THE TYPE KIMMERIDGIAN

Five ostracod zones are here stated for the Dorset Kimmeridge Clay, two in the lower and three in the upper division. Unfortunately there is a gap in the zonal scheme between the two lowermost and the three uppermost zones (covering the ammonite zones from the upper *Eudoxus* to near the top of the *Scitulus* Zone) due to the lack of the ostracods in these beds.

### 1. ZONE OF *GALLIAECYTHERIDEA DISSIMILIS* OERTLI S. STR.

This Zone extends from the base of the Kimmeridge Clay (top of Ringstead Coral Bed) to the middle of the *Mutabilis* Zone. It is characterized by the dominance of *G. dissimilis* OERTLI s. str. and the top of the Zone is marked by the disappearance of this species. Higher up in the Lower Kimmeridge Clay (*Eudoxus* Zone) there are occurrences of a similar form (KILENYI 1969, plate 24, figs. 15–20) which are distinctly larger than the typical *G. dissimilis* OERTLI s. str. and show a characteristic postero-ventral bulge. From stratigraphically higher levels in the Lower Kimmeridgian of Denmark occur specimens of *Galliaecytheridea dissimilis* OERTLI s. l. with an extremely accentuated posteroventral extension. Thus these larger specimens from the Dorset Kimmeridge Clay are transitional between *G. dissimilis* OERTLI s. str. and the above mentioned Danish specimens and probably represent a transition subspecies.

The base of the Zone is not established in the Kimmeridgian Clay as the zonal index, *G. dissimilis* OERTLI s. str. extends down to the *Cautisnigrae* Zone (Upper Oxfordian) in Dorset and elsewhere. *Mandelstamia* (*M.*) *angulata* KILENYI makes its first appearance in the basal Kimmeridgian, but as it has not been found elsewhere, not much stratigraphical reliance can be placed upon it. Very important is, however, the negative evidence of *Lophocythere multicostata* OERTLI, a species that dies out in the highest Oxfordian and indeed no species of this genus crosses the Oxfordian-Kimmeridgian boundary.

The following species occur in the Zone (species marked \* are confined to the Zone):

- \* *Galliaecytheridea dissimilis* OERTLI s. str.
- Amphicythere (A.) confundens* OERTLI
- Amphicythere (A.) pennyi* KILENYI
- \* *Amphicythere (A.) sphaerulata* KILENYI
- Cytherella recta* SHARPOVA
- Eocytheropteron (E.) decoratum* (SCHMIDT)
- Galliaecytheridea confundens* KILENYI
- Galliaecytheridea dorsetensis* nov. sp.
- Galliaecytheridea fragilis* KILENYI
- \* *Galliaecytheridea gracilis* GLASHOFF
- Galliaecytheridea postrotunda* OERTLI
- Galliaecytheridea punctata* KILENYI
- Macrodentina (M.) cicatricosa* MALZ
- Macrodentina (P.) parvapunctata* KILENYI
- Macrodentina (P.) proclivis* Malz s. l.
- \* *Mandelstamia (M.) angulata* KILENYI
- Mandelstamia (M.) rectilinea* MALZ
- Orthonotacythere interrupta* TRIEBEL
- \* *Paracypris* sp. C OERTLI
- Procytheropteron* sp. 1 KILENYI
- \* *Protocythere rodewaldensis* (KLINGLER)
- \* *Rectocythere (L.)* sp. 1 (KILENYI)
- Schuleridea triebeli* (STEGHAUS)

## 2. ZONE OF *GALLIAECYTHERIDEA ELONGATA* KILENYI

The base of the Zone lies approximately in the *Mutabilis* Zone. It is extremely well and sharply defined by the first appearance of the zonal index, *G. elongata* KILENYI, *Exophthalmocythere fuhrbergensis* STEGHAUS and *Nodophthalmocythere tripartita* MALZ.

The following species occur in the Zone (species marked \* are confined to the Zone):

- \* *Galliaecytheridea elongata* KILENYI
- Cytherelloidea paraweberi* OERTLI
- Cytherelloidea weberi* STEGHAUS
- \* *Dicrorygma (O.) reticulata* BRUUN CHRISTENSEN
- \* *Exophthalmocythere fuhrbergensis* STEGHAUS
- Galliaecytheridea confundens* KILENYI

- \* *Galliaecytheridea dissimilis* OERTLI (*large var.*)
  - Galliaecytheridea dorsetensis* nov. sp. (confined to the lower part of the zone)
- \* *Galliaecytheridea* cf. *mandelstami* (LJUBIMOVA)
- \* *Galliaecytheridea* sp. 1 KILENYI
- \* *Macrodentina* (*M.*) *maculata* MALZ
  - Macrodentina* (*P.*) *parvapunctata* KILENYI
  - Macrodentina* (*P.*) *proclivis* MALZ s. l.
  - Macrodentina* (*P.*) *steghausi* (KLINGLER) s. l.
  - Macrodentina* (*M.*) sp. 1 KILENYI
  - Mandelstamia* (*M.*) *rectilinea* MALZ
- \* *Nodophthalmocythere tripartita* MALZ
  - Orthonotacythere interrupta* TRIEBEL (confined to the lower part of the zone)
  - Schuleridea* (*S.*) *triebeli* (STEGHAUS) s. l. (confined to the lower part of the zone)

The upper limit of the Zone is undefined due to the lack of ostracods in the type section – no doubt the result of the unsuitable lithologies for the extraction of microfossils – but certainly includes a part – if not the whole of the *Eudoxus* Zone.

### 3. ZONE OF *MANDELSTAMIA* (*X.*) *MACULATA* KILENYI

The paucity of species makes the definition of this zone rather tentative. The first appearance of the zonal index is taken as the lower limit whereas the upper limit of the Zone is based on the appearance of the succeeding *G. spinosa* fauna. Nevertheless the fauna is very distinct (species marked \* are confined to the Zone):

- \* *Mandelstamia* (*X.*) *maculata* KILENYI
- \* *Cytheropteron* sp. KILENYI
- \* *Eocytheropteron aquitanum* (DONZE)
- Schuleridea* (*S.*) *moderata* n. sp.

### 4. ZONE OF *GALLIAECYTHERIDEA SPINOSA* KILENYI

This Zone has again a very characteristic and easily recognizable fauna. The lower limit is taken at the first appearance of *Mandelstamia* (*X.*) *tumida* n. sp., *Galliaecytheridea spinosa* KILENYI and *Orthonotacythere pustulata*

KILENYI, the upper limit is very sharp, being marked by the simultaneous disappearance of the whole faunal assemblage of the Zone. No corresponding break in lithology can be observed, the upper zonal limit falling within the *Lingula* shales.

The following species occur in the Zone (species marked \* are confined to the Zone):

- \* *Galliaecytheridea spinosa* KILENYI
- \* *Aalenella (D.) gracilis* nov. sp.
- \* *Aalenella (D.) inornata* (KILENYI)
- \* *Dicrorygma (O.) brotzeni* BRUUN CHRISTENSEN
- \* Indet. gen B. sp. 1 KILENYI
- \* *Mandelstamia (X.) tumida* nov. sp. (confined to the lower part of the zone)
- \* *Monoceratina* sp. 1 and sp. 2 KILENYI
- \* *Orthonotacythere pustulata* KILENYI
- \* *Orthonotacythere* sp. KILENYI
- \* *Paracypris problematica* KILENYI
- \* *Paracypris* sp. 1 KILENYI
- \* *Protocythere sigmoidea* STEGHAUS (confined to the upper part of the zone)
- \* *Protocythere nealei* KILENYI (confined to the upper part of the zone)
- Schuleridea (S.) moderata* n. sp. (confined to the lower part of the zone)

## 5. ZONE OF *GALLIAECYTHERIDEA POLITA* KILENYI

The presumably topmost ostracod zone of the Kimmeridgian has a very limited fauna of two species only; *Galliaecytheridea polita* KILENYI and *Macrodentina (M.) foveata* MALZ. Yet the assemblage is characteristic as neither of these species have been found in beds below or above.

The presence of *Galliaecytheridea compressa* nov. sp. in the Portland Sand and in the uppermost 10 ft. of the Kimmeridge Clay (cf. p. 43-44) shows that a local range zone of *G. compressa* may be extended down in the Kimmeridgian.

## RECOGNITION OF THE KIMMERIDGIAN OSTRACOD ZONES IN OTHER AREAS

The biostratigraphical subdivision of the type section of the Kimmeridgian in Dorset makes it possible to correlate other biostratigraphical units directly with the Kimmeridgian Stage. In the subsequent pages, the authors make only a rough outline of such a correlation from other areas in Northern and Western Europe to the Dorset area, as information of most of these areas is based on the literature. While problems as the demarcations of Lower and Upper Kimmeridgian, and the recognition of species from the Dorset zones in other areas are discussed, detailed correlations with the Kimmeridgian is not attempted in this paper. Such detailed correlations are not practicable, until direct correlations between the different areas permit a more or less precise correlation to the type Kimmeridgian of Dorset, but this is outside the scope of this work.

### NORTH GERMAN BASIN

Marine Kimmeridgian deposits occur near the Dutch border, and the area had direct marine connection to the Polish Basin. The North German Basin was limited towards the North by the Ringkøbing-Funen Height of Denmark. The deposits are exposed in several localities in Northwest Germany and have been studied on the basis of ostracod faunas by KLINGLER (1955) and SCHMIDT (1955). Many palaeontological papers about ostracods have been published on the basis of material from boreholes (KLINGLER, MALZ and MARTIN 1962, MALZ 1957, 1958 a, b, MARTIN 1958, 1959, SCHMIDT 1954, STEGHAUS 1951, 1953, and TRIEBEL 1954). Added to those are papers with biostratigraphical evaluations of the Kimmeridgian ostracod faunas of Northwest Germany (KLINGLER 1956, BISCHOFF and WOLBURG 1963) and a paper dealing with ostracods from the Kimmeridgian of Northeast Germany (WIENHOLZ 1968).

The Upper Jurassic in Northwest Germany is divided into Unterer, Mittlerer, and Oberer Malm, which have been subdivided in numbered biostratigraphical zones. The Kimmeridgian includes the whole of the Mittlerer Malm (Kimmeridge) and the lowermost part of Oberer Malm:

Portlandian . . . . .	Münster Mergel (Oberer Malm 5-3)
Upper Kimmeridgian	{ ? Eimbeckhäuser Plattenkalk (Oberer Malm 2) Gigas - Schichten (Oberer Malm 1)
Lower Kimmeridgian	{ Ober-Kimmeridge (Mittlerer Malm 3) Mittel-Kimmeridge (Mittlerer Malm 2) Unter-Kimmeridge (Mittlerer Malm 1)
Oxfordian . . . . .	Korallenoolith (Unterer Malm 6-4)

The following ostracod species from the different zones in the chrono-stratigraphical type section of Kimmeridgian have been found in the North German Basin:

#### A. LOWER KIMMERIDGIAN

The two ostracod zones of the Lower Kimmeridgian of Dorset are clearly recognizable in the North German Basin and they seem to be the equivalents of the Mittlerer Malm 1-2. The following species are common to both areas.

##### 1. Zone of *Galliaecytheridea dissimilis* OERTLI s. str.

Occurrence of the indexfossil *G. dissimilis* OERTLI in North-West Germany has only been reported by GLASHOFF (1964, p. 38), who found the species in the Mittlerer Korallenoolit and Unter-Kimmeridge. The other species from the Zone are:

- Galliaecytheridea dissimilis* OERTLI s. l.
- Amphicythere (A.) confundens* OERTLI
- Eocytheropteron (E.) decoratum* (SCHMIDT)
- Galliaecytheridea gracilis* GLASHOFF
- Galliaecytheridea postrotunda* OERTLI
- Orthonotacythere interrupta* TRIEBEL
- Protocythere rodewaldensis* (KLINGLER)
- Schuleridea (S.) triebeli* (STEGHAUS) s. l.

##### 2. Zone of *Galliaecytheridea elongata* KILENYI

The index fossil *G. elongata* KILENYI does not seem to occur in the North German Basin, but the following species are in common with the type section of Dorset:

- Cytherelloidea weberi* STEGHAUS
- Cytherelloidea paraweberi* OERTLI
- Exophthalmocythere fuhrbergensis* STEGHAUS

- Macrodentina (M.) maculata* MALZ  
*Macrodentina (P.) steghausi* (KLINGLER) s. l.  
*Orthonotacythere interrupta* TRIEBEL  
*Schuleridea (S.) triebeli* (STEGHAUS) s. l.

#### B. UPPER KIMMERIDGIAN

Only two of the species of the Upper Kimmeridgian in Dorset occur in the North German Basin, and therefore it is not possible to make a direct correlation of ostracod zones between the two areas.

*Protocythere sigmoidea* STEGHAUS and *Dicrorygma (O.) brotzeni* BRUUN CHRISTENSEN from the *G. spinosa* Zone occur in North Germany. The first in Mittleren Kimmeridge and older deposits. The latter in the lower part of Mittleren Kimmeridge, and in Münster Mergel.

### NORTH WEST POLISH BASIN

This area comprises the North West Polish Lowlands, the Northeastern Germany, and Scania in South Sweden. A number of biostratigraphical papers with lists of ostracod species have recently been published by Polish micropaleontologists (BIELECKA & STYK 1963, 1964, 1968) which allow us to give a reasonably complete list of species from the Polish Lowlands. These publications are supplemented by papers by OERTLI, BROTZEN, and BARTENSTEIN (1961), and BRUUN CHRISTENSEN (1965, 1968, various manuscripts) from Scania and Southeastern Denmark.

The deposits in this North West Polish Basin are mostly composed of clays and limestones, but in many parts they have not been investigated and described in detail. In the most northern part of the basin, in Scania, the Kimmeridgian deposits comprise the more or less sandy Fyledal Clay locally with thin beds of limestones (BRUUN CHRISTENSEN 1968) with sandy beds without ostracods below and above this formation.

The ostracod faunas from the basin show a marked biostratigraphic connection to the North German Basin throughout the Kimmeridgian and a somewhat less pronounced connection to the East to basins in the U.S.S.R. A connection to the North Western Danish Embayment through the Danish-Polish Trough existed in the Lower Kimmeridgian, while a faunal barrier between the two basins came into being in the Upper Kimmeridgian. These relations appear by comparisons between the whole faunas in the basins as well as by the faunal development in the Fyledal Clay.

As in North Germany, the Polish and the Danish geologists employ the stratigraphical term Kimmeridgian for the Lower Kimmeridgian, while deposits of Upper Kimmeridgian Times have been classified as Portlandian (cf. BRUUN CHRISTENSEN 1968) or Bononian.

A comparison of the ostracod faunas in the North West Polish Basin with the faunas from the type deposits of Kimmeridgian in Dorset shows that the following species are in common and are found in respectively Lower Kimmeridgian (= dolny and gorny kimmeryd) and Upper Kimmeridgian (= svodkowy bonon):

#### A. LOWER KIMMERIDGIAN

##### 1. Zone of *Galliaecytheridea dissimilis* OERTLI s. str.

This Zone seems to be recognizable by having following species in common with the Dorset area:

- Galliaecytheridea dissimilis* OERTLI s. l.
- Amphicythere (A.) confundens* OERTLI
- Eocytheropteron (E.) decoratum* (SCHMIDT)
- Galliaecytheridea dorsetensis* n. sp.
- Galliaecytheridea postrotunda* OERTLI
- Macrodentina (P.) proclivis* MALZ s. l.
- Protocythere rodewaldensis* (KLINGLER)
- Orthonotacythere interrupta* TRIEBEL
- Schuleridea (S.) triebeli* (STEGHAUS) s. l.

##### 2. Zone of *Galliaecytheridea elongata* KILENYI

The following species are in common with those of the Zone in Dorset:

- Cytherelloidea paraweberi* OERTLI
- Exophthalmocythere fuhrbergensis* STEGHAUS
- Galliaecytheridea dissimilis* OERTLI s. l.
- Macrodentina (P.) proclivis* MALZ s. l.
- Orthonotacythere interrupta* TRIEBEL
- Schuleridea (S.) triebeli* (STEGHAUS) s. l.

#### B. UPPER KIMMERIDGIAN

The three ostracod zones of the Upper Kimmeridgian can not be recognized in the North West Polish Basin. Few species such as *Dicrorygma (O.) brotzeni* BRUUN CHRISTENSEN and *Protocythere sigmoidea* STEGHAUS are in common between the two areas.

### NORTH WEST DANISH EMBAYMENT

The Danish Embayment is the northwestern part of the Danish-Polish Trough. The Jurassic and Lower Cretaceous ostracod faunas from this area have been studied by BRUUN CHRISTENSEN mainly on basis of material

from boreholes. Very little has as yet been published about the faunas of Kimmeridgian Age. The area of Scania (BRUUN CHRISTENSEN 1968a, b) naturally belongs to the North West Polish Basin, while the Kimmeridgian deposits found in boreholes in Northern Jylland naturally belong to a North West Danish Embayment separated from the North West Polish Basin in the Upper Kimmeridgian by a faunal barrier.

The Kimmeridgian deposits of the North West Danish Embayment consists of a relatively thick series of sand and clay formations (fig. 3). Different ostracod faunas from brackish-marine deposits near the margin of the basin to marine ones in the middle of the basin have been recognized.

All the Kimmeridgian ostracod zones of Dorset with exception of one, have been found in the North West Danish Embayment, and elements of ostracod faunas from the type Portlandian can as well be recognized. The following species from the Zones of Dorset occur in the area:

#### A. LOWER KIMMERIDGIAN

##### 1. Zone of *Galliaecytheridea dissimilis* OERTLI s. str.

*Galliaecytheridea dissimilis* OERTLI s. str.

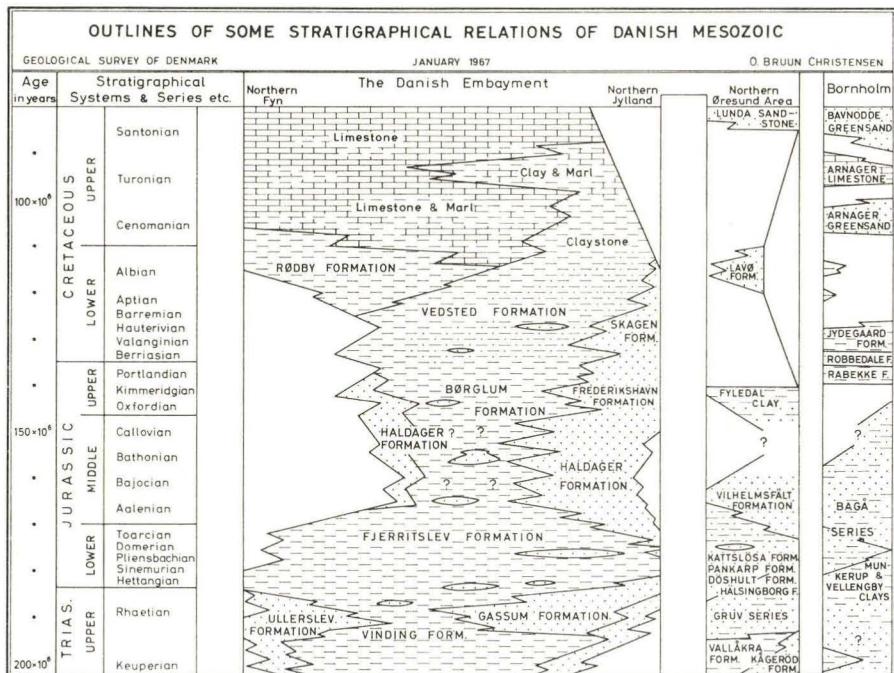

Fig. 3. An outline with some of the lithostratigraphical units of the northwestern and southeastern Danish Embayment and their geochronological and regional relations. Based largely on LARSEN (1966).

- Galliaecytheridea dorsetensis* n. sp.  
*Galliaecytheridea gracilis* GLASHOFF  
*Galliaecytheridea postrotunda* OERTLI  
*Mandelstamia (M.) rectilinea* MALZ  
*Orthonotacythere interrupta* TRIEBEL  
? *Protocythere rodewaldensis* (KLINGLER)  
*Schuleridea triebeli* (STEGHAUS) s. l.

## 2. Zone of *Galliaecytheridea elongata* KILENYI

- Galliaecytheridea elongata* KILENYI  
? *Dicrorygma (O.) reticulata* BRUUN CHRISTENSEN (see p. 50)  
*Galliaecytheridea dissimilis* OERTLI s. l.  
*Galliaecytheridea dorsetensis* n. sp.  
*Mandelstamia (M.) rectilinea* MALZ  
*Orthonotacythere interrupta* TRIEBEL  
*Schuleridea (S.) triebeli* (STEGHAUS) s. l.

## B. UPPER KIMMERIDGIAN

### 3. Zone of *Mandelstamia (X.) maculata* KILENYI

This Zone does not seem to be recognizable in the Danish Embayment since *Mandelstamia (X.) maculata* KILENYI does not seem to occur in the area. *Schuleridea (S.) moderata* n. sp., which is found in this Zone in Dorset, occurs in the *G. spinosa* Zone in the Danish Embayment.

### 4. Zone of *Galliaecytheridea spinosa* KILENYI

- Galliaecytheridea spinosa* KILENYI  
*Aaleniella (D.) gracilis* n. sp.  
*Aaleniella (D.) inornata* (KILENYI)  
*Dicrorygma (O.) reticulata* BRUUN CHRISTENSEN (see p. 50)  
*Mandelstamia (X.) tumida* n. sp.  
*Orthonotacythere pustulata* KILENYI  
*Protocythere sigmoidea* STEGHAUS  
*Schuleridea (S.) moderata* n. sp.

### 5. Zone of *Galliaecytheridea polita* KILENYI

Few specimens of *G. polita* KILENYI have been found in the Danish Embayment, but the occurrence of *Galliaecytheridea compressa* nov. sp. and some other species indicate faunas of Lower Portlandian Age above the Kimmeridgian faunas.

## PARIS BASIN

The ostracod fauna of the Paris Basin and its vertical distribution is based largely on material described from the Vernon 1 borehole (80 km NW of Paris) by OERTLI (1957) with additional data by MALZ (1958) from three localities (E and W of Paris), GUYADER (1962) (borehole in Le Havre) and OERTLI (1963). The fauna is predominantly from the Lower Kimmeridgian.

### A. LOWER KIMMERIDGIAN

#### 1. Zone of *Galliaecytheridea dissimilis* OERTLI s. str.

This zone is clearly recognizable in the Vernon borehole with its characteristic faunal assemblage. The lower boundary coincides precisely with the Kimmeridgian/Oxfordian boundary as OERTLI (1957) marks it on his distribution chart. We consider the upper limit of the zone to be in approximately the middle of OERTLI's "Kimmeridgien inferieur, partie moyen".

The characteristic assemblage consists of:

- Galliaecytheridea dissimilis* OERTLI s. str.
- Amphicythere (A.) confundens* (OERTLI)
- Eocytheropteron (E.) decoratum* (SCHMIDT)
- Schuleridea (S.) triebeli* (STEGHAUS) s. 1.

The whole fauna is very similar to that of the zone in Dorset but with some important differences. Absent from the Paris Basin is *Macrodentina (M.) cicatricoda* (the dominant species of the Zone in Dorset) and there is no trace of the genus *Mandelstamia* species of which are in common in Dorset.

#### 2. Zone of *Galliaecytheridea elongata* KILENYI

This zone is also easily recognizable in the Vernon borehole. The base of it is marked by the association of *Exophthalmocythere fuhrbergensis* and *Dicrorygma (O.) reticulata*. These are joined by *Orthonotacythere interrupta*, *Galliaecytheridea wolburgi* s. 1., *Schuleridea triebeli* s. 1. The top of the profile is situated in this zone.

GUYADER (1962 p. 26) mentions an ostracod faunule from the Le Havre borehole (Zone des "calcaire coquilliers") which appears to belong to *G. dissimilis* and basal *G. elongata* Zones.

### B. UPPER KIMMERIDGIAN

The close similarity which exists between the Lower Kimmeridgian faunas of the Paris Basin and Dorset is reduced to practically nil in the Upper

Kimmeridgian. Only one species, *Eocytheropteron (E.) aquitanum* is common to both localities (Boulogne sur le Mer, OERTLI, 1963) suggesting the probable presence of the *Mandelstamia (X.) maculata* Zone here.

### SOUTH WEST FRANCE

Upper Kimmeridgian ostracods were described from this area by MALZ (1958) and DONZE (1960). The fauna is totally different from that of the Upper Kimmeridgian of Dorset and no correlation is possible although *Eocytheropteron (E.) decoratum* occurs in both localities.

### SWISS JURA

OERTLI (1959) described an extensive Upper Jurassic fauna from a large number of localities in the Swiss Jura. The stratigraphical range of his samples spreads from the Lower Oxfordian to the Upper Kimmeridgian, although only two samples cover the basal part of the latter. In spite of the fact that seven species are common to the Lower Kimmeridgian of Dorset and the Swiss Jura, very great differences exists between the two areas. The most important is the complete absence of *Galliaecytheridea* here, a genus stratigraphically so important in all the other localities. Only very tentative correlations can therefore be made.

The *Galliaecytheridea dissimilis s. str.* Zone is indicated by a fauna which includes *Amphicythere (A.) confundens*, *Protocythere rodewaldensis*, *Eocytheropteron (E.) decoratum*, *Cytherelloidea weberi* and *Schuleridea (S.) triebel s. l.* The base of the zone coincides with the Oxfordian/Kimmeridgian boundary as shown by OERTLI (1959 text fig. 3). The *Galliaecytheridea elongata* Zone cannot be recognized.

## ALPHABETICAL LIST OF OSTRACOD SPECIES IN THE KIMMERIDGIAN OF NORTHERN AND WESTERN EUROPE

The following list is based on publications dealing with the ostracod faunas of the areas dealt with in this paper. In addition five species which are described for the first time are included.

The name of each species in the list is followed by its recorded presence in the areas considered, the letter L representing an occurrence in the Lower and U in the Upper Kimmeridgian, according to the authors' correlations with the type section. The column on the extreme right gives the most recent reference to the species or the page number in this paper where it is discussed in detail. Only those species are annotated this way which are stratigraphically important or have a complex synonymy.

The list does not give the full complement of species mentioned from Northern and Western Europe as a number of taxa with dubious identities had to be excluded. For example some species in the Polish literature are mentioned by the name of the genus followed by the designation "sp. sp." and these have not been included. On the other hand species from other areas treated with open nomenclature are incorporated as separate identity for these can be assumed without much doubt. The exclusion of a certain number of the Polish species from the list is to a certain extent counterbalanced by the inclusion of all the species from Scania.

*Galliaecytheridea compressa* n. sp., which occurs in the Portland Sand of Dorset and the Børglum Formation of the Danish Embayment, has been reported by BARKER (1966) from the topmost part of the Kimmeridge Clay of Dorset. As the present authors have not found the species there it has not been included into the following list.

The list shows 201 species of ostracods in the Kimmeridgian of Northern and Western Europe. There are 98 species in deposits of Upper Kimmeridgian age, and 139 in those of Lower Kimmeridgian in age. 36 species are common to both.

## STRATIGRAPHICAL AND REGIONAL CONCLUSIONS

In this work the authors have given only the species and their presence or absence in those deposits which in the basin mentioned have been classified as either Upper or Lower Kimmeridgian.

A study of the composition of the faunas with a compilation of ostracod assemblages and correlation of these between the seven areas of deposition will have great stratigraphical and palaeoecological importance. In the present work, only the composition of the faunas in the particular areas of deposition in Northern and Western Europe from the entire Upper and Lower Kimmeridgian will be set in relation to the type profiles for the Upper and Lower Kimmeridgian in Dorset and the stratigraphical distribution of the species which have been found in the type section will be examined in the various areas.

Figs. 4-7 (p. 36) show the number of species occurring in the various areas of deposition and the extent to which these areas have species in common. In the Lower Kimmeridgian (fig. 5 p. 36) relatively many species are common to these areas. The largest percentages of species in common are found between the North German Basin, the Paris Basin, and the North West Polish Basin. In the area of South West France no Lower Kimmeridgian ostracods have been found. In the Upper Kimmeridgian (fig. 7, p. 37) the distribution of species shows that a clear Southwest-Northeast trending faunal barrier developed, separating an Upper Jurassic North Sea Basin, comprising the Dorset area and the North West Danish Embayment of subsidence, from a Mid-European Region including the North German Basin, the North West Polish Basin, and the Paris Basin. At the same geological time the faunal similarity with the areas of South-Western France and the area in Switzerland is somewhat less developed. The area of South-Western France differs from the others in having more or less limnic environments. In the Swiss Jura in the Upper-Kimmeridgian deposits there are species of ostracods, and these have all been found also in deposits classified as Lower Kimmeridgian in other areas.

The faunal barrier between the North Sea Basin and the Mid-European Region, which became effective in the Upper Kimmeridgian, may be shown to be present also in the Portlandian. This barrier appears more clearly

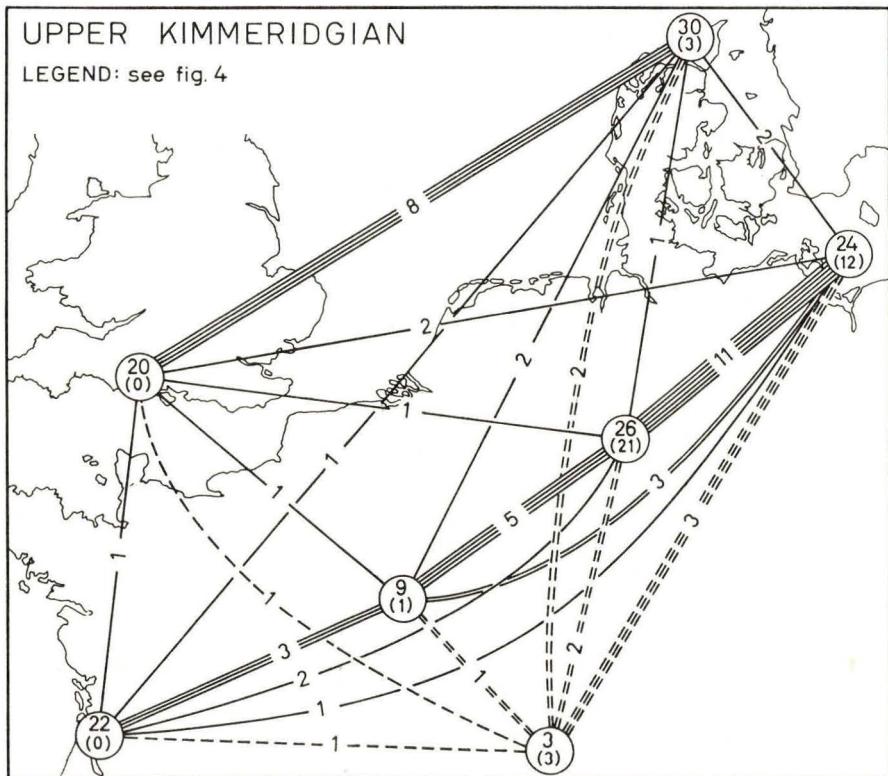

Fig. 7.

when, comparing the number of species of the different areas of deposition, those species which at one or more places have been found both in the Upper and the Lower Kimmeridgian are excluded (fig. 6, p. 37). This may perhaps be due to the uncertainty in the exact placing of the boundary between the Upper and the Lower Kimmeridgian in these areas, but is probably more likely to be due to the fact that in the areas of the North Sea Basin there are no sequences of ostracod faunas showing continuity of development between Lower and Upper Kimmeridgian.

Thus, for instance in the Dorset area there are no species in the ostracod faunas in common to both Lower and Upper Kimmeridgian.

Several of those species which in the deposits of the North Sea Basin are found in the Upper Kimmeridgian seem to be closely related to or identical with species which in the Mid-European Region of deposition are found mainly in the Lower Kimmeridgian. For example species of *Macrodentina*, which occur throughout the whole of the Kimmeridgian in the Mid-European Region, a few species of this genus found in the entire Kimmeridgian of the North Sea Basin show close affinity to species from the Lower Kimmeridgian of Northwest Germany. The genus *Mandelstamia* is – with one exception – found only in the North Sea Basin. This exception is the species *Mandelstamia inflata*, which is found only in the Mid-European Region. The genus *Galliaecytheridea* is widely distributed in the Lower Kimmeridgian over the entire area of Northern and Western Europe. It is also common in the North Sea Basin throughout the Upper Kimmeridgian and the Portlandian. But in the Mid-European Region, species of this genus have been found only early in the Upper Kimmeridgian. Species of the genera *Cytherella* and *Cytherelloidea* are only scantily represented in the Kimmeridgian of the North Sea Basin, and in the North West Danish Embayment none have been found. This effective faunal barrier between the North Sea Basin and the Mid-European Region originating at the time of transition from Lower to Upper Kimmeridgian is probably due to several factors.

There are facies differences between the two regions. The deposits of the Mid-European Region consist to a large extent of limestones, while the deposits in the North Sea Basin are developed mainly as clayey sediments, usually non-calcareous. Furthermore, many of the deposits in the Mid-European Region are more or less brackish or limnic. These differences in the conditions of deposition are, however, not sufficient to explain the mutually exclusive nature of the Upper Kimmeridgian ostracod faunas of the two regions. A physical barrier in the form of land between the two areas of deposition might explain the great differences in the faunas as well as in the lithological development. Such an area of land (Kimbria) could, during some short intervals in the Kimmeridgian and Portlandian have been overcome by the sea. Such a small marine ingressions took place once

in the Danish Embayment in the Upper Portlandian (Lower Purbeckian), forming the only direct marine connection between the North West Danish Embayment and the North West Polish Basin during the time interval from Lower Kimmeridgian to Hauterivian (BRUUN CHRISTENSEN 1970).

The ostracod faunas of the Upper Kimmeridgian of the North Sea Basin show some affinities to faunas described from the Volga-Ural region of the U.S.S.R. (LJUBIMOVA, 1955) including the type section of the Volgian Stage (Boreal Realm). Chronostratigraphical correlation of the Volgian with the Upper Kimmeridgian of the North Sea area is, however, impossible at present as biostratigraphical evidence is largely lacking and chronostratigraphical correlations over such distances are not possible without convincing evidence. Possible future discoveries of genuine chronostratigraphical evidence would solve this difficulty. The uncertainty in the correlation of biostratigraphical units of the areas considered with the units of the Kimmeridgian Stage in Dorset, and the use of this as a standard for a geological time is, however, considerably smaller than the uncertainty would be by the similar use of the Volgian Stage in a completely different basin at a much greater distance.

The possibilities of chronostratigraphical correlation are in this case presumably more to be sought among physical rather than among biological factors. It is possible that an extensive boreal inland sea was in existence in the Upper Jurassic (HALLAM 1969). A study of the conditions connected with this hypothesis may open the possibility of using as chronostratigraphical evidence certain regionally widespread physical changes in the sea which left their marks directly on these deposits (such as eustatic movements, sudden temperature changes or changes in salt content etc.).

## DESCRIPTION OF SPECIES

SUBCLASSIS OSTRACODA LATREILLE 1806

Ordo *Podocopina* MÜLLER 1894

Familia *Cytherellidae* SARS 1866

Genus *Cytherelloidea* ALEXANDER 1929

### ***Cytherelloidea paraweberi* OERTLI 1957**

*partim* 1951 *Cytherelloidea weberi* STEGHAUS, p. 207, pl. 14 figs. 3, 5 (non figs. 4–6).

?*partim* 1955 *Cytherelloidea weberi* STEGHAUS – SCHMIDT, p. 51.

1957 *Cytherelloidea paraweberi* OERTLI, p. 65, pl. 1 figs. 12–15.

1959 *Cytherelloidea paraweberi* OERTLI-OERTLI, p. 18, pl. 2 figs. 26–27.

1964 *Cytherelloidea paraweberi* OERTLI-GLASHOFF, p. 52.

*non* 1966 *Cytherelloidea paraweberi* OERTLI-BARKER, p. 457, pl. 3, figs. 7–9, p. 485, pl. 9, figs. 1–2.

1968 *Cytherelloidea paraweberi* OERTLI-BIELECKA & STYK, fig. 2.

1969 *Cytherelloidea paraweberi* OERTLI-KILENYI, p. 116, pl. 23, figs. 8–9, textfig. 5a.

#### *Diagnosis*

Carapace quadrangular. Each valve with a peripheral continuous ridge parallel and equidistant from the margin. A curved median rib branches out from the upper one, descends to the middle of the valve, where it turns to run parallel with dorsal margin.

#### *Remarks*

The specimen illustrated by BAKER (1966 figs. 7–9) differs too much from *C. paraweberi* OERTLI to be included in this species. It is much thicker in dorsal aspect, especially in the posterior part of the carapace.

#### *Distribution*

DORSET: In *Gallaecytheridea elongata* Zone, Kimmeridge Clay.

NORTH GERMANY: Unteres Kimmeridge.

NW. POLAND: Astart and dolny kimeryd.

PARIS BASIN: Kimméridgien inférieur (moyen).

SWISS JURA: Mittleres-Oberes Kimmeridge.

Familia *Schulerideidae* MANDELSTAM 1959

Subfamilia *Schulerideinae* MANDELSTAM 1959

Genus *Schuleridea* SWARTZ & SWAIN 1946

**Schuleridea (Schuleridea) moderata** nov. sp.

Plate I figs. 1a–i

1969 *Schuleridea* sp. 1 KILENYI, p. 119, pl. 23, figs. 34–39.

1969 ?*Schuleridea* sp. 2 KILENYI, p. 119, pl. 24 fig. 1.

(MS) *Schuleridea (Schuleridea) moderata* BRUUN CHRISTENSEN & KILENYI – BRUUN CHRISTENSEN (MS)

*Derivation of Name.* From Latin *moderatus*, moderate.

*Holotype.* A carapace; Plate I, figs. 1a–b. D.G.U. Catalogue No. 1970 – OBC – 1.

*Type Locality.* Borehole Fjerritslev No. 1, D.G.U. File No. 24.216.

*Type Stratum.* Dark claystone; 474–480 m, 147 cm below the top of the core.  
Børglum Formation. Upper Kimmeridgian.

*Material in the Sample.* Nine carapaces, three valves and fragments.

*Diagnosis*

A weakly but densely punctate species of *Schuleridea (Schuleridea)* with rounded periphery and a weak overlap by the left valve. The posterodorsal margin is rounded, long, and relatively steep with the rounded posterior end near the ventral margin and a weakly developed posterodorsal angle less than fourth of the valve's length from the posterior end.

*Affinities*

The species is closely related to *Schuleridea* n.sp. aff. *triebeli* (STEGHAUS) in MALZ (1958a, pl. 2 fig. 14–16), but the dorsal margin on the left valve is more flat and there are fewer porecanals in the marginal zone.

*Description*

The carapace is oviform. The anterior margin is circular, rounded. The ventral margin is straight to weakly convex. In the posterior part, the ventral margin curves upwards towards the rounded posterior end, situated in the lowermost fourth of the valves in females. In male valves the posterior end is nearly circularly rounded into the posterodorsal margin, with continued smoothness into the dorsal margin. Above the posterior end the posterodorsal margin on females has a small convexity to the posterior cardinal angle about one fourth of the valve's length from the posterior end, and one fourth of the valve's height from the greatest height of the carapace. The dorsal margin on the females is nearly semicircular. The greatest height is situated just anterior of the middle of the carapace. The overlap of the left valve is nearly the same along the whole periphery. In dorsal aspect the lateral surfaces are smoothly arched, and the carapace is pointed terminally.

The lateral surfaces are finely and densely punctate. The eye spot is relatively weakly developed. The anterior marginal zone contains 20–30 radial pore canals, mostly straight, only in the uppermost part a few are bent upwards. In the posterior marginal zone 12–15 radial porecanals have been found. The hinge and the muscle scars as in other species of the genus, but the accomodation groove is very weakly developed.

<i>Measurements:</i>	<i>Length</i>	<i>Height</i>
Females .....	0.65–0.67 mm	0.43–0.44 mm
Males .....	0.78 mm	?48 mm

#### *Distribution*

NORTH WEST DANISH EMBAYMENT: Børglum Formation, Upper Kimmeridgian.

SOUTH ENGLAND: Kimmeridge Clay, *Mandelstamia (X.) maculata* Zone and the lowermost part of *Galliaecytheridea spinosa* Zone, Upper Kimmeridgian in Dorset. Smaller specimens of the species have been found in a sample from the Kimmeridge Clay, Cumnor Hills near Oxford.

### Genus *Galliaecytheridea* OERTLI 1957

#### *Galliaecytheridea dissimilis* OERTLI 1957 s. l.

1957 *Galliaecytheridea dissimilis* OERTLI, p. 655, pl. 1 figs. 32–39, pl. 2 figs. 40–44.

1964 *Galliaecytheridea dissimilis* OERTLI – GLASHOFF, p. 38, pl. 4, figs. 8–11.

1968 *Galliaecytheridea dissimilis* OERTLI – BIELECKA & STYK, fig. 2.

1969 *Galliaecytheridea dissimilis* OERTLI – KILENYI, p. 120, pl. 24, figs. 8–20, textfigs. 3a, 5d.

(MS) *Galliaecytheridea dissimilis* OERTLI – BRUUN CHRISTENSEN (MS).

#### *Original Diagnosis*

“Espece du genre *Galliaecytheridea* avec les caractéristiques suivantes: inégalité frappante des valves: valve gauche beaucoup plus haute sur les parties dorsale et ventrale. Arrière triangulaire assez pointu, surtout pour la valve droite. Surface finement ponctuée”. (OERTLI 1957, p. 655).

#### *Remarks*

This species occurs in the Dorset profile as two morphological subspecies. The stratigraphically higher specimens of *G. dissimilis* (*large var.*) are characterized by their size, and by rhomboidal outline caused by the development of a postero-ventral bulge. Some specimens from the Danish Embayment have this posteroventral bulge in a very strongly developed form. In the lowermost part of the Kimmeridge Clay *G. dissimilis* s. str. has been found.

### Distribution

PARIS BASIN: Oxfordien supérieur ("Séquanien") to partie inférieure du Kimméridgien inférieur.

DORSET: Upper Oxfordian to Lower Kimmeridgian (*Galliaecytheridea dissimilis* s. str. Zone and *G. elongata* Zone in Kimmeridge Clay).

N. GERMAN BASIN: Mittlerer Korallenoolith to unterer Kimmeridge.

NW. POLISH BASIN: Orgow & Raurak & Astart (Oksford) and dolny kimeryd.

NW. DANISH EMBAYMENT: Lowermost Børglum Formation (Uppermost Oxfordian and Lowermost Kimmeridgian).

### ***Galliaecytheridea compressa* nov. sp.**

Plate I figs. 2a-f, plate II figs. 1a-d

1966 *Galliaecytheridea wolburgi* (STEGHAUS) — BARKER, p. 450, pl. 2 figs. 1-8.

(MS) *Galliaecytheridea compressa* BRUUN CHRISTENSEN & KILENYI — BRUUN CHRISTENSEN (MS).

*Derivation of Name.* From Latin *compressus*, compressed.

*Holotype.* A female carapace, plate I figs. 2a-b. No IO 2763 deposited in the British Museum (Natural History) (BARKER's collection).

*Type Locality.* Hounstout Cliff, Dorset.

*Type Stratum.* Bed 7, Portland Sand.

### Diagnosis

A punctate species of *Galliaecytheridea* with the central valve surfaces more or less concave seen in dorsal view. The central part of the posterodorsal margin has a slight but characteristic angle with an occasionally developed posteroventral spine in the otherwise evenly rounded curve.

### Affinities

The species has to be separated from *G. wolburgi* (STEGHAUS) by the concavity of the central part of the valves, and from *G. crendonensis* BARKER and *G. spinosa* KILENYI by having an angle near the middle of the nearly circularly curved posteroventral margin, and considerably less pointed posterior ends. On *G. wolburgi* (STEGHAUS) there is a distinct angle between the rather straight posteroventral margin and the straight ventral margin. *G. polita* KILENYI lacks the central compression of the valves and is not punctate.

### Distribution

DORSET: The species has been found in samples from the entire lower part of the type section of the Portlandian (Portland Sand) and perhaps

from the uppermost part of the Kimmeridge Clay just below the Massive Bed and the Black Nore Sandstone:

"Samples from beds 10 ft. below the Massive Bed to the Lower Parallel Band at Hounstout Cliff have yielded a characteristic ostracod fauna, as also have beds at West Weare Cliff from 10 ft. below the Black Nore Sandstone to the Basal Shell Bed". (BARKER 1966, pp. 447–448).

NW. DANISH EMBAYMENT: Uppermost Børglum Formation (Portlandian).

### **Galliaecytheridea dorsetensis nov. sp.**

Plate II figs. 3a–d, ? 4a–d

part. 1957 *Cyprideis wolburgi* (STEGHAUS) – OERTLI, p. 657, pl. 2 figs. 56–58 (non fig. 59–60), (non pl. 3 fig. 61–68).

part. 1968 *Galliaecytheridea wolburgi* (STEGHAUS) – BRUUN CHRISTENSEN.

1969 *Galliaecytheridea wolburgi* (STEGHAUS) – KILENYI, p. 121, pl. 24 figs. 21–27.  
(MS) *Galliaecytheridea dorsetensis* BRUUN CHRISTENSEN & KILENYI – BRUUN CHRISTENSEN (MS)

*Derivation of Name.* From Dorset, South England.

*Holotype.* A left valve. No HU 2.J.13.1 (KILENYI 1969, pl. 24 fig. 21) Geology Department- University of Hull.

*Type Locality.* Black Head, Dorset.

*Type Stratum.* *Galliaecytheridea dissimilis* Zone (Zone of *Rasenia cymodoce*) about ten feet above Ringstead Coral Bed, Kimmeridge Clay (Lowermost Kimmeridgian).

*Material.* 347 valves and carapaces from Kimmeridge Clay, Dorset.

#### *Diagnosis*

A punctate species of the genus *Galliaecytheridea* with convex ventral margin, which curves smoothly into the posteroventral margin. The dorsal margin is straight with a slight concavity in the posterior half and a gently convex anterior part especially in the left valve. Greatest height is situated near the middle of the carapace.

#### *Affinities*

The species has to be separated from *G. wolburgi* s. str. by the convex ventral margin. In *G. wolburgi* s. str. the ventral and dorsal margins are nearly straight and parallel. The juvenile carapaces are difficult to distinguish from specimens of *G. minuta*, *G. elongata* or *G. postrotunda*.

#### *Distribution*

DORSET: *Galliaecytheridea dissimilis* Zone and *G. elongata* Zone, Lower Kimmeridge Clay.

PARIS BASIN: Kimméridgien inférieur.

NW. POLISH BASIN: *Amphicythere (A.) semisulcata* – *Schuleridea (S.) triebeli* Fauna, Fyledal Clay, Lower Kimmeridgian.

**Galliaecytheridea elongata** KILENYI 1969

1969 *Galliaecytheridea elongata* KILENYI, p. 123, pl. 25 figs. 6–12.

1969 *Galliaecytheridea trapezoidalis* KILENYI, p. 123, pl. 25, figs. 13–19, textfigs. 3f, 5g.  
(MS) *Galliaecytheridea elongata* KILENYI – BRUUN CHRISTENSEN (MS).

*Diagnosis*

A relatively small punctate species of *Galliaecytheridea* with slightly concave posterodorsal margin and slightly pointed posterior end in the horizontal median of the carapace. Left valve overlaps clearly the right one dorsally and ventrally. The anterior margin is evenly curved and more flattened in the dorsal part, especially on the female carapace. The dorsal and ventral margins on left valves of the latter are curved slightly, tapering from the mid-line of the carapace, where the largest height is situated. Carapace of males is long with nearly straight and parallel ventral and dorsal margins.

*Remarks*

The females of this species were described by KILENYI (1969) as *G. trapezoidalis*.

*Distribution*

DORSET: *G. elongata* Zone, Lower Kimmeridge Clay.

NW. DANISH EMBAYMENT: Børglum Formation, Lower Kimmeridgian.

**Galliaecytheridea gracilis** GLASHOFF 1964

Plate II figs. 2a–b

1964 *Galliaecytheridea gracilis* GLASHOFF – p. 39, pl. 4 figs. 12–18.

1969 *Galliaecytheridea* sp. 2 KILENYI, p. 131, pl. 27 figs. 1–4.

(MS) *Galliaecytheridea gracilis* GLASHOFF – BRUUN CHRISTENSEN (MS)

*Diagnosis*

A small species of the genus *Galliaecytheridea* with nearly rounded posterior end and convex ventral margin. The anterior margin is evenly curved ending at the largest height of the carapace, a third (♀) or a fourth (♂) of the length of the carapace from the anterior end. Posterior part of dorsal margin is straight.

*Distribution*

DORSET: Upper Oxfordian and Lowermost Kimmeridgian (*G. dissimilis* Zone).

N. GERMAN BASIN: Oberer Korallenoolith to Basis Kimmeridge.

NW. DANISH EMBAYMENT: Frederikshavn and Børglum Formations, Lower Kimmeridgian.

**Galliaecytheridea oertlii nov. sp.**

Plate III figs. 1a–i

part. 1957 *Galliaecytheridea wolburgi* STEGHAUS-OERTLI, p. 657 pl. 3 figs. 63–68 (non pl. 2 figs. 56–60 or pl. 3 figs. 61–62, 66).

part. 1968 *Galliaecytheridea wolburgi* STEGHAUS-BRUUN CHRISTENSEN.

(MS) *Galliaecytheridea oertlii* BRUUN CHRISTENSEN & KILENYI – BRUUN CHRISTENSEN (MS).

*Derivation of Name.* In honour of Dr. H. J. OERTLI, Pau, France.

*Holotype.* A female carapace. Plate III figs. 1b–c. D.G.U. Catalogue No. 1970 – OBC – 18.

*Type Locality.* Borehole Øresund (The Sound) No. 1A near Elsinore, D.G.U. File No. 188.345.

*Type Stratum.* Sample No. 23, core 51.70–53.15 m, 73 cm below top of the core.

Fyledal Clay (Beds with clay and limestone, dark grey, greenish and bluish, hard, shelly Lower part of *Mandelstamia inflata* Zone (BRUUN CHRISTENSEN MS) of Lower Kimmeridgian age.

*Material*

Several hundred valves from the type stratum.

*Diagnosis*

A smooth or very weakly punctate species of *Galliaecytheridea* with pointed posterior end and very slightly convex ventral margin. Anterior margin is almost semicircular. The greatest height is about one-fifth of the valve's length from the anterior, near the anterior cardinal angle. The dorsal margin is straight. The posterior cardinal angle is well marked and is situated near the posterior end. The posterodorsal margin is long and straight in females and is short and rounded in males. In dorsal view the carapace is almost elliptical in shape, lacking any central concavity. The larval stages have commonly a posteroventral spine which is rarely present in adults.

*Remarks*

This species is close to *Paleocytheridea grigorievi* Ljubimova (1958, p. 561, pl. III fig. 4) from the Lower Kimmeridgian of the U.S.S.R.

*Distribution*

NW. POLISH BASIN: Zone of *Mandelstamia inflata* (Bruun Christensen MS), Fyledal Clay, Lower Kimmeridgian. Scania.

PARIS BASIN: Kimméridgien inférieur.

### **Galliaecytheridea polita KILENYI 1969**

1969 *Galliaecytheridea polita* KILENYI, p. 128, pl. 26, figs. 21–26, textfig. 36.  
 (MS) *Galliaecytheridea polita* KILENYI – BRUUN CHRISTENSEN (MS).

#### *Diagnosis*

A smooth species of *Galliaecytheridea* with the left valve only slightly larger than the right one. Dorsal and ventral margins nearly straight and parallel. The curved posteroventral margin has a slight angle at the central part at least on female left valves. In dorsal view the lateral surfaces are smooth and convex.

#### *Affinities*

The species is very close in outline to *G. compressa* nov. sp., which is characterised by punctate valve surfaces and lateral compression in the central part of the valve.

#### *Remarks*

Valves from the Danish material show that the species has to be classified as a true *Galliaecytheridea*.

#### *Distribution*

DORSET: *Galliaecytheridea polita* Zone, Uppermost Kimmeridge Clay.  
 NW. DANISH EMBAYMENT: Uppermost Børglum Formation or lower-most Vedsted Formation, Uppermost Kimmeridgian and Portlandian.

### **Galliaecytheridea postrotunda OERTLI 1957**

- 1957 *Galliaecytheridea postrotunda* OERTLI, p. 656, pl. 2 figs. 45–55.
- 1959 *Galliaecytheridea postrotunda* OERTLI – OERTLI, p. 25, pl. 3, fig. 89.

 (MS) *Galliaecytheridea postrotunda* OERTLI – BRUUN CHRISTENSEN (MS).

#### *Original diagnosis*

“Espèce du genre *Galliaecytheridea* avec les caractères suivants: contour latéral en forme d’ovale allongé. Arrière bien arrondi; point extrême à mi-hauteur ou un peu au-dessous. Angle cardinal postérieur bien marqué. Bord antérieur souvent avec plusieurs dents fines. Épine sur la valve droite près du bord postéroventral. Surface ponctuée, peu dans le milieu, avec une grande densité dans la partie ventrale et les extrémités.” (OERTLI 1957, p. 656).

### Distribution

PARIS BASIN: Oxfordien supérieur to Kimméridgien moyen.

DORSET: Corallian to Lower Kimmeridge Clay (Lower part of the Zone of *G. dissimilis* s. str.)

NW. POLISH BASIN: Upper Oxfordian to Lowermost Kimmeridgian (Ar-gow to dolny kimeryd).

N. GERMAN BASIN: Unterer Kimmeridge.

NW. DANISH EMBAYMENT: Haldager Formation and Børglum Formation (Upper Oxfordian and Lower Kimmeridgian).

### ***Galliaecytheridea spinosa* KILENYI 1969**

Plate III figs. 2a-c; textfig. 8

1969 *Galliaecytheridea spinosa* KILENYI, p. 128, pl. 26, figs. 10-20.

1969 *Galliaecytheridea* sp. 3 KILENYI, p. 132, pl. 27 figs. 15-16.

(MS) *Galliaecytheridea spinosa* KILENYI - BRUUN CHRISTENSEN (MS).

### Diagnosis

Species of *Galliaecytheridea* with extremely pointed posterior end. Two or three little spines usually on posterior extremity. Sexual dimorphism very strong, males much longer than females. Surface of valve pitted.

### Remarks

This species is close to *Galliaecytheridea crendonensis* BARKER 1966 but in *G. spinosa* the dorsal and ventral margins are nearly parallel, whereas in *G. crendonensis* these margins taper strongly towards the posterior. *G.*

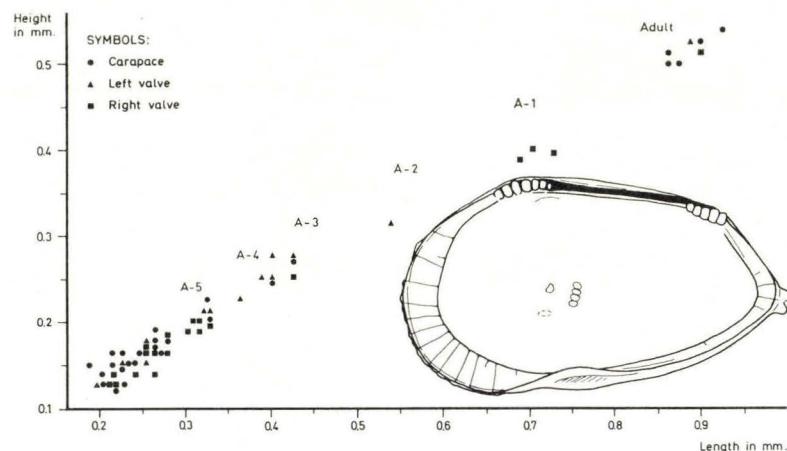

Fig. 8. Scattergram showing relations between numbers, lengths, and heights of *Galliaecytheridea spinosa* KILENYI s. l. from boring Fjerritslev No. 1, core 474-480 m, 147 cm below the top of the core. Outline of the adult right valve from sample shown.

*crendonensis* has also a more strongly developed caudal process, which is in a posteroventral position and not at mid-height as in *G. spinosa*.

#### Distribution

DORSET: *G. spinosa* Zone, Upper Kimmeridge Clay.

NW. DANISH EMBAYMENT: Børglum and Frederikshavn Formations, Upper Kimmeridgian.

#### **Galliaecytheridea wolburgi** (STEGHAUS 1951)

 non 1969 *Galliaecytheridea wolburgi* (STEGHAUS) – KILENYI, p. 121, pl. 24 figs. 21–27,  
 text figs. 3c, 5c.  
 ? (MS) *Galliaecytheridea cf. wolburgi* (STEGHAUS) – BRUUN CHRISTENSEN (MS).

#### Diagnosis

A large species of *Galliaecytheridea* with long and parallel dorsal and ventral margins. The posterior end lies well above the mid-height of the valve. The posteroventral margin is straight, steep and long with well marked angle to the ventral margin.

#### Remarks

A number of species have been described under the name of *G. wolburgi* and it is very difficult to clear up the present confusion without examining the material in question. *G. wolburgi minuta* (SCHMIDT 1955) may well be a separate species and has been considered as such in the present paper (see plate II figs. 5a-b).

#### Subfamilia *Cuneocytherinae* MANDELSTAM 1960

##### Genus *Dicrorygma* POAG 1962

1968 *Dicrorygma (Orthorygma)* sp. WIENHOLZ, pl. 4 fig. 42.  
1969 *Dicrorygma (Orthorygma)* sp. 1 (KILENYI) — KILENYI, p. 137, pl. 31 figs. 32–33.  
(MS) *Dicrorygma (Orthorygma) brotzeni* BRUUN CHRISTENSEN (MS).

#### *Original diagnosis*

“A dense punctate species of *Dicrorygma (Orthorygma)* with slightly convex dorsal margin, slightly developed cardinal angle and approximately rounded posterior termination”. (BRUUN CHRISTENSEN 1965, p. 19).

#### *Remarks*

The species has an exterior outline very reminiscent of *Mandelstamia ignobilis* LJUBIMOVA 1955 as this has been described and figured by LJUBIMOVA (1955, p. 66, pl. 7 figs. 3a–b) from the Lower Volgian in the Buzuluk Region of the U.S.S.R. The description includes no morphological feature diverging from that of *D. (O.) brotzeni*.

### Distribution

NW. POLISH BASIN: Common in deposits of Upper Kimmeridgian Age. In Scania the species occurs in the Zone of *Mandelstamia inflata* from uppermost Lower Kimmeridgian and from Upper Kimmeridgian deposits (BRUUN CHRISTENSEN MS). In northeastern Germany the species seems to occur in deposits of Portlandian Age (WIENHOLZ 1968).

DORSET: Zone of *Galliaecytheridea spinosa* Kilenyi, Upper Kimmeridge Clay.

NORTH GERMAN BASIN: Kimmeridge.

 (MS) *Mandelstamia (Mandelstamia) rectilinea* MALZ – BRUUN CHRISTENSEN (MS).

### Original diagnosis

“Eine Art der Gattung *Mandelstamia* mit folgenden Besonderheiten: Seitenflächen mit grossen, rundlichen Grübchen besetzt. In Dorsalansicht ist die Wölbung der Seitenflächen durch einen flachen Randstreifen vom Vorderrand abgesetzt, die grösste Breite liegt hinter der Mitte, am Hinterende stossen die Seitenflächen in einem spitzen Winkel zusammen. Sexual-Dimorphismus ausgeprägt.” (MALZ 1958 p. 38).

### Remarks

The strongly developed sexual dimorphism of the species, with large males, having inflated carapace, with often complicated reticulation on the posterior part can be observed on all the specimens in the Danish Embayment.

### Distribution

DORSET: Zones of *Galliaecytheridea dissimilis* and *G. elongata*, Lower Kimmeridge Clay, and probably in Oxfordian.

NW. DANISH EMBAYMENT: Børglum Formation. Lower Kimmeridgian (Zones of *G. dissimilis* and *G. elongata*).

File No. 24.216.*Type Stratum.* Dark claystone; 474-480 m, 147 cm below the top of the core. Børglum Formation. Upper Kimmeridgian.*Material in the Sample.* Seven carapaces and 21 valves.*Diagnosis*

A reticulate species of *Mandelstamia* (*Xeromandelstamia*) with nearly parallel dorsal and ventral margins and with a posterodorsal tubercle, situated one-third of the valve's length from the posterior cardinal angle. A second, less strongly developed but elongated posteroventral tubercle may also be present. These tubercles are less conspicuous in the adult stage than in instars. In the males the individual pits of the reticulate ornamentation are subdivided. In females the ornamentation is uniform.

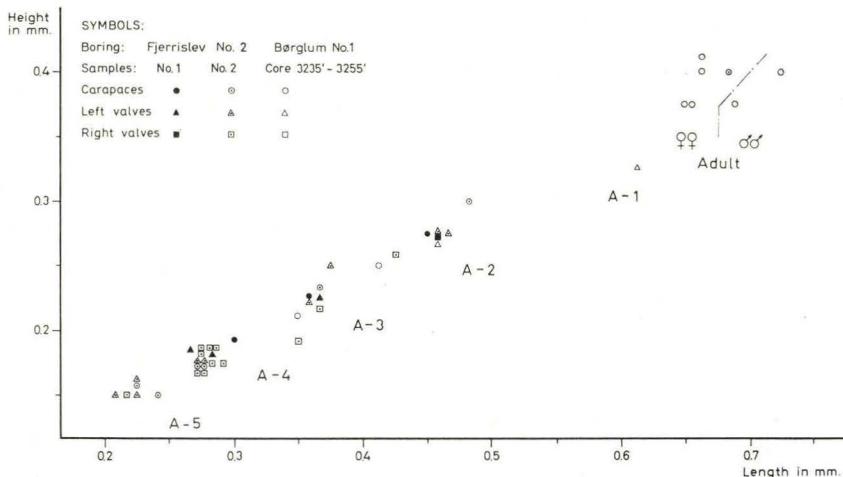

Fig. 9. Scattergram showing relations between numbers, lengths, and heights of *Mandelstamia* (*Xeromandelstamia*) *tumida* nov. sp. in three samples. Fjerritslev No. 2 with samples No. 1 and No. 2 are the uppermost sample and the type sample from core 474-480 m.

### *Distribution*

NW. DANISH EMBAYMENT: Børglum and Frederikshavn Formation,  
Lower? and Upper Kimmeridgian.

DORSET: Lowermost *G. spinosa* Zone, Upper Kimmeridgian. Kimmeridge Clay.

? Subfamilia *Paradoxostominae* BRADY and NORMAN 1889

Genus *Aalenella* PLUMHOFF 1963

### *Diagnosis*

Small, elongated, and laterally compressed species with straight dorsal margin. The left valve overlaps the right valve along the anterior, ventral, and posterior margins. Along the dorsal margin the right valve comes up over the dorsal margin of the left valve, and this overlap is especially distinct at the anterior cardinal angle. The adductor scars consist of four small, close-set scars arranged in a gently curved ventrodorsal line. Anterodorsally of this is a round antennal scar. The marginal zones are of median width with well developed vestibules, and with few and straight radial pore canals. The hinge in the right valve consists of a smooth often weakly developed furrow and two smooth, elongated, and not well developed terminal teeth.

Subgenus *Aalenella* (*Aalenella*) PLUMHOFF 1963

Type Species. *Aalenella* (*Aalenella*) *compressa* PLUMHOFF 1963.

### *Diagnosis*

Small, smooth species of the genus *Aalenella* with long and straight dorsal margin and rounded posterior end. Anteroventrally of the adductor scars two mandibular scars can be observed.

### *Remarks*

Only two species have so far been included in this genus (the type species and *Aalenella* sp. 1 PLUMHOFF 1963), and both are from the lower part of the Middle Jurassic in Germany. *Aalenella* sp. 1 has not such strongly converging dorsal and ventral margins as the type species.

Subgenus *Aalenella* (*Danocythere*) nov.

Type Species. *Aalenella* (*Danocythere*) *gracilis* nov. sp.

Derivation of Name. *Dano-* is a short, clear, and specific prefix to the common generic name *-cythere*.

*Diagnosis*

Species of the genus *Aalenella* with a relatively short and straight dorsal margin. The posterior end is pointed and somewhat drawn out. The vestibule in the anterior marginal zone is short and deep.

*Remarks*

Mandibular scars have not been seen in the material.

The exterior features of the genus *Pyrocytheridea* LJUBIMOVA 1955 are very similar to *Aalenella*, especially the larval stages of this species, but it has a different and more complicated hinge. In the species of *Pyrocytheridea* vestibules have not been demonstrated.

The larvae of the species of *A. (Danocythere)* show in the exterior features remarkable similarities to the adult specimens of the older subgenus *A. (Aalenella)*.

***Aalenella (Danocythere) gracilis* nov. subgen. et sp.**

Plate IV figs. 2a-f; textfig. 10.

1969 ?*Pyrocytheridea* sp. KILENYI, p. 33, pl. 27 figs. 25-26.

(MS) *Aalenella (Danocythere) gracilis* BRUUN CHRISTENSEN and KILENYI - BRUUN CHRISTENSEN (MS).

*Derivation of Name.* Of Latin *gracilis*, slender.

*Holotype.* Right valve. Plate IV fig. 2a textfig. 10. D.G.U. Catalogue No. 1970 - OBC - 34.

*Type Locality.* Borehole Fjerritslev No. 1, D.G.U. File No. 24.216.

*Type Stratum.* Dark claystone 474-480 m, 147 cm below the top of the core. Børglum Formation. Upper Kimmeridgian.

*Material in the Sample.* 19 carapaces and five valves.

*Diagnosis*

A small, smooth species of *Aalenella (Danocythere)* with flattened lateral surfaces. The posterior terminal process is pointed and somewhat drawn out.

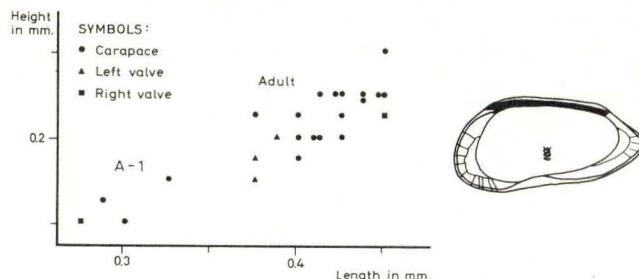

Fig. 10. Scattergram showing relations between numbers, lengths, and heights of *Aalenella (Danocythere) gracilis* nov. subgen. et sp. from the type stratum. Outline of the holotype is figured. The widths of adult carapaces are 0.15-0.19 mm.

### Description

In lateral view the carapace is oviform, with pointed ends. The dorsal margin is straight, the anterior cardinal angle is weakly developed and is situated one-fourth of the valve's length from the anterior. The posterior cardinal angle is one-fifth of the valve's length from the posterior. The posterior margin is symmetrically rounded in an even curve, just below the mid-height of the valve. The anterior margin joins smoothly the nearly straight ventral margin, which continues in a slightly convex form to join the posterior end. The posterodorsal margin is either slightly concave or more commonly straight or slightly convex.

In dorsal view the carapace is gently arched and the central portions are nearly parallel. At a distance of one-sixths of the carapace's length from the anterior and posterior the sides of the valve begin to converge strongly. In frontal view the greatest breadth of the carapace is between one-third and half of the height from the ventral and the lateral surfaces of the valves meet in a right angle at the dorsal margin. In cross section the ventral part of the carapace varies from the anterior to the posterior. In the anterior part the outline is somewhat pointed, at midway it is semicircular and in the posterior half the lateroventral surfaces extend below the ventral margin.

The left valve is larger than the right with strong overlap along the anterior, ventral and posterior margins. Along the straight dorsal margin the periphery of the right valve is raised above that of the left.

The valve surface is smooth and shiny.

The adductor muscle scars consist of four extremely small scars arranged in a near vertical row. In front of them is a large, rounded antennal muscle scar. The normal pore canals are spread irregularly over the valve and seem to be present in relatively small number.

Eye spots have not been observed. The marginal zone is relatively broad. The zone of concrescence has about the same width along its entire length. A deep vestibule is developed in the middle of the anterior and posterior marginal zone, from which the irregularly distributed radial pore canals radiate outwards. These are straight, numbering 10–12 along the anterior and 4–5 along the posterior margin.

The hinge in the left valve consists of a long smooth median bar, the ends of which are bent slightly downwards. Two terminal sockets, smooth and elongated, are situated above the ends of the median bar. These sockets are open towards the dorsal margin to receive corresponding teeth from the right valve. The median hinge element of the right valve consists of a long, smooth bar, which is in a dorsal position compared with the median bar of the left valve. The terminal teeth in this valve are separated from the median bar by a shallow groove which opens outwards to the dorsal margin. The terminal teeth are the continuation of the selvage and are bent slightly inwards, parallel with the median bar.

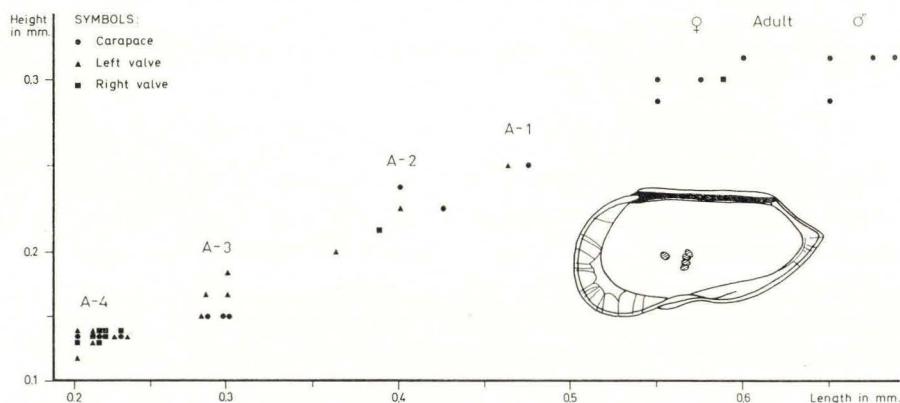

Fig. 11. Scattergram showing relations between numbers, lengths, and heights of *Aalenella (Danocythere) inornata* (KILENYI) from boring Fjerritslev No. 1, core 474–480 m. Outline of the adult right valve is figured. The widths of adult females and males are 0.18–0.20 mm and 0.19–0.20 mm.

Juvenile valves have narrow marginal zones. Dimorphism has only been observed in the adult stage.

Relatively few of the adult specimens show a pointed and drawn out posterior end. This characteristic is more clearly seen in the right valve, where the posterodorsal margin can be weakly concave. All three single left valves and most of the carapaces in the material from Denmark have convex posterodorsal margins.

#### *Distribution*

ENGLAND: Dorset, Upper Kimmeridge Clay, Zone of *Galliaecytheridea spinosa* KILENYI, and Cumnor Hill, near Oxford.  
NW. DANISH EMBAYMENT: Børglum and Frederikshavn Formation. Upper Kimmeridgian.

#### ***Aalenella (Danocythere) inornata* (KILENYI 1969)**

Plate IV figs. 3a–g; textfig. 11.

1969 ?*Acrocythere inornata* KILENYI, p. 144, pl. 28 figs. 40–43.

(MS) *Aalenella (Danocythere) inornata* (KILENYI) – BRUUN CHRISTENSEN (MS).

#### *Diagnosis*

A large and reticulate species of the subspecies *Aalenella (Danocythere) inornata* characterised by longitudinal lists in the central part of the lateral valve surface.

### *Remarks*

The name of the species is misleading. Originally the name of *ornata* was suggested for the Danish material, as opposed to two smooth species (BRUUN CHRISTENSEN MS), but the type material from Dorset was so poorly preserved, that special methods of colouring had to be used before the reticulation was recognized.

The species shows great exterior similarities to *Palaeocytheridea bakirovi* MANDELSTAM 1947 from the Middle Jurassic deposits of Mangeschlak in the Caspian Sea. These exterior similarities are greater than to *P. parabakirovi* MALZ 1962 from Middle Callovian in Northwest Germany. Both of these species have dentate hinge elements and no vestibules (cf. MALZ 1959, 1962).

### *Distribution*

DORSET: *Galliaecytheridea spinosa* Zone, Upper Kimmeridge Clay.

NW. DANISH EMBAYMENT: Børglum and Frederikshavn Formations, Upper Kimmeridgian.

Familia *Progonocytheridea* SYLVESTER-BRADLEY 1948

Genus *Rectocythere* MALZ 1958

Subgenus *Rectocythere* (*Rectocythere*) MALZ 1958

Type Species. *Rectocythere* (*Rectocythere*) *iuglandiformis* (KLINGLER 1955).

### *Diagnosis*

Species of the genus *Rectocythere* without lateroventral ridge or alae. The marginal zone without vestibules as inner margin and the line of concrescence coincidence.

Subgenus *Rectocythere* (*Lydicythere*) nov.

Type Species. *Rectocythere* (*Lydicythere*) *scandia* nov. sp.

Derivation of Name. *Lydi-* is a short, clear and specific prefix to the common generic name *-cythere*.

### *Diagnosis*

Small species of the genus *Rectocythere* with more or less irregular knobs on the lateral surfaces, with a vertical median sulcus along nearly the entire height of the valve, and a lateroventral ridge with ala-like structure of knobs. Inner margin and the line of concrescence do not coincide, and there are narrow vestibules along the marginal zones.

### *Remarks*

MALZ (1966, p. 408) mentioned that "indet. gen. sp. 1" OERTLI, BROTZEN, and BARTENSTEIN 1961 has to be included in *Rectocythere* on the basis of the general outline and the number of marginal pore canals. Further studies of this species *R. (Lydicythere) scandia* nov. sp. and other species from the Danish Embayment have supported such a view. Moreover, the species *Kleiana? pustulata* KLINGLER 1955 has to be included on the same basis in the genus. An English species (indet. gen. A. sp. 1 KILENYI 1969, p. 137, pl. 31, fig. 20–21) could well be a species of *Rectocythere (Lydicythere)* nov. subgen. The species *Mandelstamia verrucifera* LJUBIMOVA 1955 from Oxfordian of U.S.S.R. is difficult to include in the subgenus because of the incomplete description given by LJUBIMOVA (1955).

All the species of *R. (Lydicythere)* nov. subgen. have so far been found in deposits of Lower Kimmeridgian Age. The, as yet unsubstantiated, occurrences in Upper Oxfordian and Upper Kimmeridgian deposits may reduce the biostratigraphical value of the new subgenus.

### ***Rectocythere (Lydicythere) scandia* nov. sp.**

Plate IV figs. 4a–f.

1961 Indet. gen. sp. 1 OERTLI, BROTZEN & BARTENSTEIN, p. 16, plate 1 figs. 7–14.

1968 *Rectocythere* (n. subgen.) aff. *R. pustulata* (KLINGLER) – BRUUN CHRISTENSEN, text fig. 1, fig. 3.

(MS) *Rectocythere (Lydicythere) scandia* BRUUN CHRISTENSEN & KILENYI – BRUUN CHRISTENSEN (MS).

*Derivation of Name.* Referring to the region of occurrence. The species has been found in Denmark and Sweden in the Fennoscandian Border Zone.

*Holotype.* A left valve, plate IV fig. 4c. D.G.U. Catalogue No. 1970 – OBC – 46. *Type Locality.* The pit of Fyleverken, Fyledalen, Scania.

*Type Stratum.* Ostracod Zone I: Light greenish, greasy clay, lower part of the Fyledal Clay. Lower Kimmeridgian.

*Material in Sample.* 28 valves from the type stratum.

### *Diagnosis*

A small species of *Rectocythere (Lydicythere)* with more or less inflated knobs, irregularly spaced on the lateral valve surfaces. Between the knobs the surface varies from smooth to finely granular or very weakly reticulate. The posterior part of the ventral rib is composed of a number of closely spaced knobs.

### *Affinities*

One of the authors (O.B.C.) sent specimens of this species from Fyledalen in Scania to Dr. Malz (Forschung-Institut Senckenberg, Frankfurt a. M.) who compared these with specimens of *Rectocythere (Lydicythere) pustu-*

*lata* (KLINGLER 1955). Dr. MALZ informs us (personal communication to O.B.C. 7.4.1967) that the two species are closely related, but can be separated on the basis of size and by the fact that the knobs on the valve surface are more conspicuous in *Rectocythere (L.) pustulata* and by the more pointed posterior end of *Rectocythere (L.) scandia*. Dr. MALZ remarks that the ventral rib, the characteristic feature of the subgenus, is present in *Rectocythere (L.) pustulata* (KLINGLER). This has not been mentioned or illustrated by KLINGLER, who only shows elongated knobs in a row along the ventral margin (1955, plate 12, fig. 15a).

#### *Distribution*

NW. POLISH BASIN: Fyledal Clay, Lower Kimmeridgian. Scania.

NW. DANISH EMBAYMENT: Børglum and Frederikshavn Formations,  
Lower Kimmeridgian.

## DANSK SAMMENDRAG

### *OSTRACODER OG BIOSTRATIGRAFI I NORD- OG VESTEUROPAS KIMMERIDGIEN*

I Nordvesteuropa inddeltes epoken øvre jura almindeligvis i aldrene oxfordien, kimmeridgien og portlandien. Etagerne (aflejringerne), der er grundlaget for disse geologiske aldre, kan studeres i typeprofiler i Sydengland. Hver af de tre etager er yderligere underdelt kronostratigrafisk i øvre og nedre afsnit på basis af lithologiske eller biostratigrafiske forhold i disse aflejninger.

Etagen kimmeridgien udgøres af den ca. 500 meter mægtige formation af Kimmeridge ler i Dorset. Denne formation er opdelt i talrige biostratigrafiske zoner ved hjælp af de fundne ammonitter (fig. 2 side 12), hvormed andre aflejninger med lignende ammonitfaunaer fra andre områder er blevet korreleret. Specielt har korrelationsmulighederne med nedre Kimmeridge ler været vellykket. Af flere årsager har dette medført, at navnet Kimmeridge de fleste steder udenfor Storbritannien oftest kun benyttes på aflejninger, der biostratigrafisk kan jävnføres med nedre Kimmeridge ler (nedre kimmeridgien). Dette har også tidligere været det mest almindelige i Danmark, hvor aflejninger, der kunne jävnføres med øvre Kimmeridge ler som regel blev klassificeret som værende af nedre portlandien alder.

I nærværende arbejde benytter forfatterne navnet kimmeridgien i engelsk betydning og udstrækker etagen til helt at omfatte Kimmeridge ler. Portlandien knytter sig derfor udelukkende til de aflejninger (Portland Beds), der i Dorset overlejrer kimmeridgien (Kimmeridge Clay).

For nylig er et studium af ostracodfaunaerne fra Kimmeridge leret blevet publiceret (KILENYI 1969). Dette ligger til grund for nærværende arbejde, hvor stratotypen for kimmeridgien biostratigrafisk opdeles i fem tydelige ostracodzoner (fig. 2 side 12) på tilstedeværelsen og udviklingen af ostracod-slægterne *Galliaecytheridea* og *Mandelstamia*. Et stort afsnit af etagen omfattende øvre del af nedre kimmeridgien og nedre del af øvre kimmeridgien samt mindre afsnit i øvre kimmeridgien indeholder dog ikke ostracoder. På basis af denne ostracodzonering og det samlede indhold af ostracoder fra etagen gennemgås faunasammensætningerne i tilsvarende aflejninger i Nord- og Vesteuropa (fig. 1 side 9). Faunasammensætningerne er kendt fra litteraturen med undtagelse af faunaerne i det Danske Sænkningsområde, hvis sammensætning ikke tidligere har været publiceret (BRUUN

CHRISTENSEN MS), og forhold vedrørende revisioner af typeprofilets ostracodarter meddeles.

Kapitlerne p. 14 og p. 18 indeholder en nærmere omtale af ostracodarterne fra de forskellige aflejringsområder, samt fra typeprofilet i Dorset. Zoneinddelingen af dette profil er ligeledes søgt genfundet i de andre områder.

Samtlige kendte ostracodarter af kimmeridgien alder i aflejringsområderne i Nord- og Vesteuropa er søgt opført i alfabetisk ordnede lister i kapitlet p. 26. Forfatterne har forsøgt at klassificere arternes stratigrafiske forekomster overvejende ved hjælp af litteraturen til nedre kimmeridgien (mrk. L i listerne) eller til øvre kimmeridgien (mrk. U) fra de syv aflejringsområder. I listerne er der anført henvisninger til den mest betydningsfulde, nyere litteratur, hvor ældre ostracodarter er blevet beskrevet. Sideangivelserne i listerne henviser til kapitlet p. 40 i nærværende arbejde, hvor nye og ældre arter er diagnosticeret og revideret. Samtlige anførte arter i de syv aflejringsområder er sammentalt med hensyn til optræden i øvre og i nedre kimmeridgien, samt i begge disse geologiske tidsafsnit i det pågældende område, samt antal arter der tid efter anden et eller flere steder optræder i begge disse geologiske tider. Ligeledes gøres der rede for områdernes fælles arter i antal og i procent ved anvendelse af en simpel binær korrelationskoefficient (Jaccards koefficient).

Det fundne talmateriale fremtræder delvis grafisk i fig. 4–7 (siderne 36–37). I fig. 5 er det samlede antal arter i de forskellige aflejringsområder fra nedre kimmeridgien indskrevet i cirkler på kortet. De i parentes anførte tal angiver antal arter heraf, der tillige forekommer i øvre kimmeridgien i det pågældende område. Mellem de enkelte områder er der med tal opført antal af fælles arter i nedre kimmeridgien. Jaccards koefficient er angivet som procent af den samlede fauna mellem to områder ved antal linier indenfor multipla af fem procent.

I fig. 6 angiver tallene i cirklerne antal arter i de respektive områder, der tid efter anden er fundet både i nedre og øvre kimmeridgien i Nord- og Vesteuropa. Tallene på enkelte forbindelseslinier mellem områderne angiver det antal arter, de pågældende områder har fælles af sådanne arter, der tid efter anden er fundet i aflejringer fra nedre og øvre kimmeridgien.

Fig. 7 illustrerer ostracodfordelingerne i øvre kimmeridgien og svarer i opbygning til fig. 5.

Af ovennævnte figurer fremgår det, at ostracodfaunaerne gennem nedre kimmeridgien som en helhed udviser et ensartet præg for Nord- og Vesteuropa. Det samme synes imidlertid ikke at være tilfældet med faunasammensætningen som helhed gennem øvre kimmeridgien. Ved sammenligninger af fig. 6, fig. 7, listerne i kapitlet p. 26 og zoneundersøgelserne i kapitlerne p. 14 og p. 18 fremgår det, at der i øvre kimmeridgien fandtes to regioner med vidt forskellige ostracodfaunaer.

Den ene region omfattede det Nordvest Danske Sænkningsområde og Dorset området. Dette synes at udgøre et sammenhængende Nordsø Bassin gennem yngste del af øvre jura, idet artsfællesskab mellem områderne også kan påvises i portlandien (BRUUN CHRISTENSEN MS).

Den anden region omfattede det Nordvest Polske Bassin, hvori det Sydøst Danske Sænkningsområde naturligt indgår, desuden det Nordtyske Bassin, Pariser Bassinet og muligvis området i Sydvestfrankrig. Disse områder har forfatterne sammenfattet under betegnelsen den Midteuropæiske Region.

Forskellene i sammensætningerne af ostracodfaunaerne de to regioner imellem kan have flere årsager. Forfatterne forestiller sig imidlertid som den vigtigste årsag til dannelse af en faunabarriere mellem regionerne, at direkte marine forbindelser i øvre del af nedre kimmeridgien blev afbrudt f. eks. mellem Dorset området og Pariser Bassinet og mellem det Nordvest Danske Sænkningsområde og det Polske Bassin. Et marint og tilsyneladende langstrakt aflejringsbassin (Nordsø Bassinet) fra Dorset til den nordlige del af Jylland fortsatte således gennem hele kimmeridgien (og i portlandien) tilsyneladende med en relativt ensartet ostracodfauna.

Disse regionale og stratigrafiske forhold bliver belyst i kapitlet p. 35, hvor den stratigrafiske betydning af ostracodslægterne *Mandelstamia* og *Galliae-cytheridea* i Nordsø Bassinet fremhæves. Disse slægters tilstedeværelse og andre forhold i ostracodfaunaerne i Nordsø Bassinet viser slægtskab med ostracodfaunaer beskrevet fra Volga-Ural området i Sovjetunionen. I dette område findes stratotypen for volgien etagen, hvis nedre dele er af kimmeridgien alder. Imidlertid er korrelationer de to områder imellem meget vanskelige på grund af de store afstande, de svage biostratigrafiske korrelationsmuligheder og manglen på kronostratigrafiske korrelationsindikatorer. De sidstnævnte skal nok snarere søges blandt fysiske end blandt biologiske faktorer i aflejringerne. Muligheden for, at der har eksisteret et fra verdenshavet afskilt øvre jurassisk, borealt indhav (HALLAM 1969) med specielle aflejringsforhold forøger udsigten til, at fysiske forandringer i dette indhav ikke kun forårsager de ret ukontrollable biologiske forandringer, men tid efter anden forårsager sådanne forandringer, at disse kan aflæses direkte i aflejringerne forskellige steder i et sådant indhav og anvendes i den kronostratigrafiske korrelation.

Kapitlet p. 40 indeholder oprettelse af syv nye arter og to nye underslægter. Ialt er 19 arter anført med diagnoser, synonymlister og redegørelser for stratigrafisk udbredelse. De anførte arter har alle tidligere været publiceret under forskellige navne, som det fremgår af synonymlistene til hver art. Af stor vigtighed har det imidlertid været at klarlægge forholdene omkring hanner og hunner hos forskellige ostracodslægter, idet blandt andet de to køn har været beskrevet som forskellige arter.

1b, female carapace, right view, holotype .....	1970–OBC–18		
1c, the same specimen, dorsal view.			
1d, male carapace in right view, paratype .....	1970–OBC–19		
1e, the same specimen, dorsal view.			
1f, larval right valve, paratype .....	1970–OBC–20		
1g, larval right valve, paratype .....	1970–OBC–21		
1h, larval left valve, paratype .....	1970–OBC–22		
1i, larval right valve, paratype .....	1970–OBC–23		
Boring Øresund No. 1A, core 51.70–53.15 m			
 Figs. 2a–c <i>Galliaecytheridea spinosa</i> KILENYI s. l. ....	.....	.....	48
2a, right larval valve .....	1970–OBC–24		
2b, female carapace, right view .....	1970–OBC–25		
2c, female carapace, right view .....	1970–OBC–26		
Boring Fjerritslev No. 1, core 474–480 m			
 Figs. 3a–f <i>Mandelstamia (Xeromandelstamia) tumida</i> nov. sp. ....	.....	.....	52
3a, left larval valve, paratype .....	1970–OBC–27		
3b, right larval valve .....	1970–OBC–28		
Boring Fjerritslev No. 1, core 474–480 m			
3c, larval carapace, right view .....	1970–OBC–29		
3d, the same specimen in dorsal view			
Boring Børglum No. 1, core 3235'–3255'			
3e, female carapace, left view, holotype .....	1970–OBC–31		
3f, the same specimen, dorsal view.			
Boring Fjerritslev No. 1, core 474–480 m			

phot. CHR. WESTERGAARD (figs. 1a–i, 2a–c, 3a, 3e–f) – O. NEERGAARD RASMUSSEN  
 (figs. 3b–d)

The specimens with numbers prefixed D.G.U. are in collection of the Geological Survey of Denmark.
